Ethereum Killers

Summary

ethereum

Ethereum is a global, open-source platform for decentralized applications. In other words, it is a decentralized blockchain platform that enables developers to build and deploy smart contracts and applications without central authority control. Unlike Bitcoin, which primarily functions as digital currency, Ethereum operates as a programmable global computer where developers can create any type of decentralized service. The platform hosts over \$14 billion in DeFi applications with hundreds of thousands of active users across financial protocols, NFT marketplaces, and gaming platforms. Its transition to Proof of Stake in September 2022 reduced energy consumption by over 99%, addressing environmental concerns while strengthening network security. The network operates through thousands of independent validator nodes that process transactions and execute smart contracts on the Ethereum Virtual Machine. Smart contracts are self-executing programs written in Solidity that automatically carry out agreements when conditions are met, eliminating intermediaries like banks or brokers. Validators stake ETH as collateral to propose and validate blocks, earning rewards for honest participation while facing penalties for malicious behavior. The EIP-1559 upgrade introduced a dynamic base fee mechanism that burns ETH with each transaction, creating deflationary pressure during high network activity when more ETH is burned than issued to validators. Vitalik Buterin proposed Ethereum in 2013, but seven co-founders helped build it, including Gavin Wood who created Solidity and the EVM technical specification, and Joseph Lubin who founded ConsenSys. The project launched in July 2015 after raising over \$18 million through crowdfunding, quickly becoming the largest blockchain developer community. Major milestones include the 2020 Beacon Chain launch, the 2021 London hard fork implementing fee burning, and the 2022 Merge to Proof of Stake. Ether (ETH) serves multiple functions: paying transaction fees (gas), staking to secure the network and earn 3-5% annual yields, serving as collateral in DeFi protocols, and purchasing NFTs and digital assets. The asset is increasingly adopted by traditional institutions, with publicly traded companies adding ETH to corporate treasuries to generate staking yields while maintaining blockchain exposure, and in 2024, the SEC approved spot Ethereum ETFs, allowing traditional investors to gain exposure through conventional brokerage accounts. Ethereum's roadmap focuses on dramatically increasing transaction capacity to over 100,000 per second, reducing confirmation times, and enhancing decentralization while maintaining security against future threats like quantum computing. cardano

Cardano is a blockchain platform built on academic research that enables smart contracts and decentralized applications while using significantly less energy than traditional cryptocurrencies like Bitcoin. What sets Cardano apart is its methodical, research-driven approach — every major feature is peer-reviewed by scientists and cryptographers before being added to the network. This careful process aims to create a more secure and stable foundation compared to platforms that prioritize speed over thorough testing. The platform's native cryptocurrency, ADA, is used to send money, pay transaction fees, and participate in network governance. Cardano uses a proof-of-stake system to process transactions, which works differently from Bitcoin's mining approach. Instead of competing to solve complex puzzles, users can "stake" their ADA — essentially locking it up temporarily — to become validators who verify transactions. The system selects validators based on how much ADA they've staked and for how long, then rewards them with additional ADA for their participation. This approach uses far less energy than traditional mining while keeping the network secure. The platform also features a two-layer design that separates basic payment transactions from smart contract operations, allowing each function to be optimized independently for better performance. ADA holders can earn staking rewards by locking up their tokens to help secure the network, vote on proposed changes to the platform, and use ADA for international money transfers with lower fees than traditional

services. Cardano was founded in 2017 by Charles Hoskinson, who previously helped create Ethereum. Hoskinson leads Input Output Global (IOG), the technology company that builds and maintains Cardano's core software. The ecosystem operates through three organizations: IOG handles technical development, the Cardano Foundation promotes adoption and standardization, and Emurgo helps businesses integrate blockchain technology into their operations. This structure distributes responsibilities across multiple groups rather than concentrating control in a single entity. In February 2025, major asset manager Grayscale Investments filed to create an exchange-traded fund (ETF) for Cardano with the U.S. Securities and Exchange Commission, which would allow traditional investors to buy ADA through their regular brokerage accounts without needing to set up cryptocurrency wallets. solana

Solana is a high-performance Layer 1 blockchain designed for mass adoption by providing a fast, secure, and low-cost environment for decentralized applications. It distinguishes itself by scaling globally without the use of complex sharding or multiple layers, instead maintaining a single, unified ledger to avoid liquidity fragmentation. This architecture allows it to process thousands of transactions per second with sub-second finality, often at a cost of less than a penny per transaction. The network operates on a unique hybrid model that combines Proof of Stake with an innovation called Proof of History, which functions as a decentralized clock to timestamp transactions. This system reduces the need for constant node communication, allowing the Sealevel engine to run non-conflicting smart contracts in parallel across multiple CPU cores. Further efficiency is gained through the Gulf Stream protocol, which reduces confirmation times by forwarding transactions to validators before the current block is finished. Founded in 2017 by Anatoly Yakovenko, Solana is now supported by the Switzerland-based Solana Foundation and significant institutional investors like Andreessen Horowitz and Polychain Capital. The platform's native token, SOL, serves as the primary currency for paying transaction fees, participating in network governance, and securing the system through staking. Solana has also seen significant institutional adoption ranging from spot Solana ETFs to major partnerships including Visa's 2025 launch of USDC settlement on the network and the tokenization of public equity by firms like Galaxy Digital. polkadot

Polkadot is a platform that allows diverse blockchains to transfer messages, including value, in a trust-free fashion; sharing their unique features while pooling their security. In brief, Polkadot is a scalable heterogeneous multi-chain technology. Polkadot is heterogeneous because it is entirely flexible and makes no assumption about the nature or structure of the chains in the network. Even non-blockchain systems or data structures can become parachains if they fulfill a set of criteria. Polkadot may be considered equivalent to a set of independent chains (e.g. a set containing Ethereum, Ethereum Classic, Namecoin and Bitcoin) except with important additions: pooled security and trust-free interchain transactability. Many of the native parachains of Polkadot will be written using a Polkadot Runtime Environment SDK (e.g. Parity Technologies' Substrate). Link: <https://polkadot.com/>

avalanche

Avalanche is a high throughput smart contract blockchain platform. Validators secure the network through a proof-of-stake consensus protocol. It is said to be fast, low cost, and environmental friendly. Link: <https://www.avax.network>
